# Time-domain CSEM modelling

using frequency- and Laplace-domain computations

Dieter Werthmüller and Evert Slob, TU Delft

20 October 2021

# Time-domain modelling with a frequency-domain code

⇒ (1) Frequency selection (2) Gridding ⇐

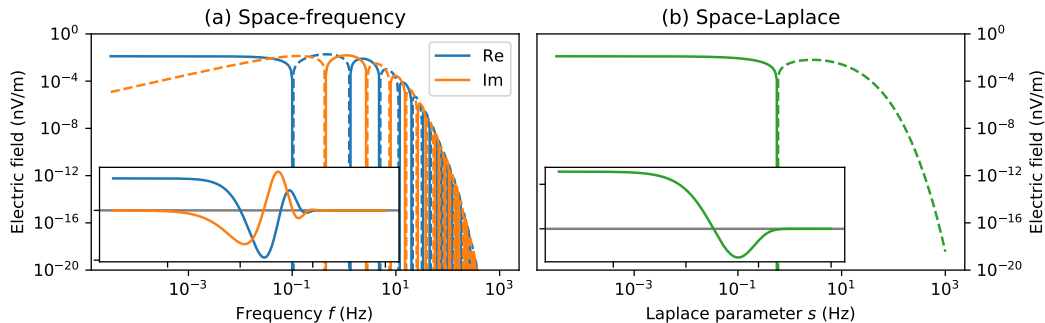

Werthmüller et al., 2021, *Fast Fourier transform of electromagnetic data for computationally expensive kernels*, GJI; DOI: [10.1093/gji/ggab171](https://doi.org/10.1093/gji/ggab171).

# Laplace-domain computation

$$i\omega \rightarrow s: \quad s\sigma \mathbf{E} + \nabla \times \mu^{-1} \nabla \times \mathbf{E} = -s\mathbf{J}_s$$

⇒ Faster (1) Computation (2) Convergence ⇐

# Laplace-to-time domain transformations

1. Design digital linear filters for the transform
2. Carry out transform for semi-analytical (layered) responses
3. Test stability

- Time-domain modelling with a frequency-domain code: 15–25 frequencies are usually enough
- Laplace-domain computation
- Laplace-to-time domain transformation
- Laplace-to-frequency domain transformation

Used open-source codes:

empymod (layered models) & emg3d (3D models), see [emsig.xyz](https://emsig.xyz).
